

- LRR: log2 of the bin's median depth over the member's autosomal median (GC-corrected where a GC track was given)
- the step fit of the track (total-variation denoising): a piecewise-constant reading in which every jump has to earn its height
- the phased fraction pooled over a window of sites (depth-weighted): at 1/2 where the homologues are equal, $1/2 + d$ or $1/2 - d$ along an event, the sign the parent of origin - in the child, below one half the paternal homologue is in excess (a paternal gain, a maternal copy lost), above one half the maternal; in a parent, below one half the event lies on the homologue not passed to the child, above one half on the one passed; hollow where the window is parted in two or more members (paralogy), which the fits and the scan leave out
- a called gain (line at the segment's mean LRR)
- a called loss
- a called copy-neutral event - a loss of heterozygosity, or a uniparental heterodisomy (drawn at zero)
- the child over the parents' mean depth, site by site, per bin (the within-family difference)
- the child's maternal copies: the LRR step fit's copies ($2 \times 2^{\text{LRR}}$) times the maternal fraction's step fit
- the child's paternal copies, the same way
- ┌ an event given from elsewhere (--events), drawn above the track
- reference lines: zero LRR, BAF at 1/2, 1/3 and 2/3; the centromere
