

- LRR: log2 of the bin's median depth over the member's autosomal median (GC-corrected where a GC track was given)
- the step fit of the track (total-variation denoising): a piecewise-constant reading in which every jump has to earn its height
- BAF: the alt-allele fraction at the member's heterozygous sites (a sample of them)
- the phased fraction pooled over a window of sites (depth-weighted) at 1/2 where the homologues are equal (a parent), reference bias out
- the phased fraction at one heterozygous site of the maternal allele (the child), of the allele passed to the child (a parent), reference bias out
- the phased fraction at one heterozygous site of the paternal allele (the child), of the allele passed to the child (a parent), reference bias out
- the child's maternal copies: the LRR step fit's copies ($2 \times 2^{\text{LRR}}$) times the maternal fraction's step fit
- the child's paternal copies, the same way
- a called gain (line at the segment's mean LRR)
- a called loss
- a called copy-neutral event - a loss of heterozygosity, or a uniparental heterodisomy (drawn at zero)
- reference lines: zero LRR, BAF at 1/2, 1/3 and 2/3; the centromere
